ASD: A Different Way of Thinking & Feeling Leads To A Different View of the World: Improving Intervention & QOL

Penn State

July 30, 2007
Nancy J. Minshew M.D.
Director, Autism Center of Excellence
University of Pittsburgh
412 246-5485
INTERVENTION CHECKLIST: Person Factors

- General level of function, FS IQ, VIQ, Vineland
- Language comprehension level, communication
- Flexibility-rigidity
- Impulsivity, overactivity
- Redirectability, motivation
- Social-emotional age, social tolerance
- Sensory issues
- Problem solving: identifies problems, plans, identifies failure, changes strategies, asks for help
INTERVENTION CHECKLIST:
Person Factors Cont’d

- Temperment
- Mood lability
- Aggression
- Seizures
- Tolerance of change (flexibility), rituals
- Obsessions, preoccupations, special interests
INTERVENTION CHECKLIST:
Environment Factors (All)

- Environmental structure/order/chaos
- Environmental noise, visuals, smells
- Autism skills of teachers; attitude of teacher
- Expectations of child=child abilities?
- Peer or adult bullying
- Transitions, lunchroom, playground, hallways, bus
- Changes in schedule, teachers, rooms, peers, etc
Observation support enhanced perception detail
Tests like Embedded Figures & unsegmented block design add empiric support but not universal
Some studies do not support local precedence
Some studies do not support lack of global precedence
Micro-analytic techniques separate out confusing factors and look just at local vs global processing
A bias toward seeing the whole (global processing) over seeing the details (local processing) has long been debated as part of the basis for behavior in autism from resistance to change to obsessions with the details a few interests over concepts and a broad range of interests. Specialized methods are used to evaluate these perceptual biases.

In verbal individuals with autism in this study, all had local processing bias but only some had global precedence.

This variability needs to be compared to performance on cognitive tests including face recognition and to behavioral flexibility/rigidity and memory for details to begin to explain the variability typical of the autism spectrum.
Cognitively the problem is with prototype formation and automatic processes as opposed to conscious verbally mediated reasoning.
Infants are born with automatic mechanisms that allow them to form Prototypical Representations of Information.
Which of these is the best example of a dog?
Which of the following two faces looks more familiar to you?
Gender Categorization

Attractiveness Ratings

Correlation of ratings by Controls vs. Autistics: $r = -.06$
Conclusions

• Individuals with autism have difficulty with categorizing atypical exemplars of categories
• While categorization improves with development, adults with autism never reach the “expertise” abilities of controls
• These deficits are seen with both faces (e.g., gender discrimination) and object categorization
• The inability to form prototypical representations of categories also impacts facial recognition skills so that distinctive faces are not remembered better than typical faces
• A lack of facial prototypes can also be seen in their not perceiving “average” or prototypical faces as attractive.
Social Emotional Impairments in Autism

- Social isolation
- Theory of mind, social cognition
- Face emotion, face identity, face gender
- Gaze and eye expression and use
- Tone of voice
- Body language
- Emotion dysregulation
- Imaging abnormalities of amygdala, FFA…
Social Emotional Immaturity: Disturbance in Affective Contact Not Included in DSM

- Capacity to experience, comprehend, and regulate emotions at a basic and cognitive level is severely impaired and unrecognized despite frequent abnormal imaging abnormalities studies of the amygdala, an emotion structure of the brain.

- Most verbal ASD adults are socially-emotionally 12-18 months to 4-5 years of age. Failure to recognize this in treatment worsens behavior and function.

Multiple organ involvement is the rule in brain disorders not caused by brain damage—because they are caused by faulty genes and these genes are present in every cell in the body.
2.27 relative risk of autism diagnosis conferred by the CC genotype at MET receptor tyrosine kinase. MET signaling is involved in neocortical and cerebellar development, immune function, and gastrointestinal repair, consistent with the multi-organ symptoms reported in autism.

Need not invoke GI or immune disease as causing brain dysfunction; same gene may cause all.

Campbell et al. PNAS 2006, 45: 16834-16839
Neurologists’ approach to understanding disease is therefore to examine all impaired AND intact abilities to define the common characteristics that will identify the underlying disease process and its location in the brain.
Disease Processes

- Infectious disease
- Vascular disease
- Tumor or mass
- Toxins (signatures like carbon monoxide)
- Developmental processes (basic form of the brain, neuron number, neuron migration, neuron organization etc)
Abnormalities in social, language, play, reasoning & complex behavior
70% mentally retarded; 30% average and above IQ
Seizures in 30%
Not deaf or blind
No long tract signs (cerebral palsy)
Bottom line: cortical gray matter, no white matter
Later caveat: unlike typical child neurology cases, no learning disabilities or visuospatial problems= distributed neural systems disorder
## Discriminant Function Analysis: Domains Without Deficits\(^3\)

What Does This Mean About Cognition?

- Information acquisition intact
- Simpler processing & abilities are intact/enhanced
- Selective impairment in complex information processing across domains e.g. tasks that require an increase in the number of cognitive processes or brain regions for task performance
3. Not a General Information Processing Disorder or both simple and complex abilities would be impacted.

4. Not a Simple Information Processing Disorder or individuals with ASD would have dyslexia, dyscalculia, and visuospatial problems (see SLI).

5. Despite title, this model though emphasizing complex information processing deficits also infers intact or enhanced basic skills.
Behavioral Example of Cognitive Profile in Autism: Details No Concepts

Jim was admitted for possible mania. He was agitated and had been sending money to television evangelists and became preoccupied with sin and being good, which he talked about constantly. The psychiatrists attempted daily to convince him to try lithium but he refused. His reason was that he took lithium on June 4, 1978 and he got a stomach ache. He went to the clinic and a scene ensued. Staff yelled at him. No amount of appeal worked to change his mind, until he was told and SHOWN there were now two forms of lithium - one was pink and one was blue. He took the bad blue before, but this time he would take the good pink. He immediately agreed to the medication. The deterioration in his behavior was the result of losing his job for asking a woman a question about her clothing, which was interpreted as sexual harassment. All structure was gone from his life. Socially-emotionally he was 3.
Detroit Learning Aptitude Test: Processing Demands of Complex Sentences

![Bar chart showing scores for different tasks: Letter Sequences, Word Sequences, Oral Directions. The chart compares autism and control groups, with significant differences marked by asterisks.](chart.png)
Dual task performance deficit in autism; *(but matched performance in single task conditions)*

Digit recall is expressed as a percentage of correct sequences.
Abstract Reasoning:
Concept Identification & Concept Formation

- 90 verbal individuals with autism >12 yrs
- 107 control volunteers
- Concept identification
  - Attribute identification
  - Rule-learning
- Concept formation
  - Self-initiated strategy
- Cognitive flexibility
- Extent to which these were dissociable skills
Results in Non-Retarded Autistic Individuals

- Concept identification intact:
  - Attribute identification
  - Rule learning
- Inflexible in applying rules in changing contexts
- Concept and strategy formation impaired
- Bottom line: adaptive function in real life poor
Reasoning Guides Behavior Across Spectrum

- Rote training of concepts, first attributes then rules
- Difficulty generalizing outside original learning setting
- Rule-bound and difficulty considering context
- Difficulty in novel situations or any situation requiring spontaneous problem solving or strategy formation
- Do not acquire the concept formation abilities that allow flexible use of or development of new strategies in novel situations. No adaptive function or generalization of learned interventions.
Bill is a young adult with autism who decided to take figure skating lessons. His mother drove to the rink several times a week. After a while, she decided to skate while he had his lesson. Bill performed his routine, but people learned to stay out of his way. He went where his program required him to go regardless of others. One day his mother forgot to note where Bill was and he ran her over, knocking her unconscious. The emergency team was called and she was given first aide and taken to the hospital. The next day she asked Bill why he did not come to her assistance, since he was an Eagle Scout with a first aide badge. He replied “It expired.”

Behavioral Example of Cognitive Profile: Rules Override Concepts
Can’t rely on them to identify problems or ask for help— the first requires concept formation and the latter is a strategy and then requires social contact—people will also get upset at their failure

Need a review of systems approach & a reporter

They will need external organizer & prioritization

May not be able to handle as much as others

Their approach to assignments may be to read everything—wont know how to reduce task
What Does This Imply About the Brain?

- Higher order circuitry of neural systems is under-developed
- Rely on lower order circuitry, which may be overdeveloped
fMRI Activation During a Spatial Working Memory Task

Healthy Individuals

Autistic Individuals
Lower functional connectivity in autism between pairs of key language areas during sentence comprehension
Autism group has lower functional connectivity but same rank order
Group differences in functional connectivity

Control group

Group with autism

Functional connectivity (z)
